Abstract

A MIMO secure two-hop wireless communication system is considered in this paper. In this model, there are no direct links between the source-destination and the source-eavesdropper. The problem is maximizing the secrecy capacity of the system over all possible amplify and forward (AF) relay strategies, such that the power consumption at the source node and the relay node is limited. When all the nodes are equipped with single antenna, this non-convex optimization problem is fully characterized. When all the nodes (except the intended receiver) are equipped with multiple antennas, the optimization problem is characterized based on the generalized eigenvalues-eigenvectors of the channel gain matrices.

I. INTRODUCTION

The use of relay nodes in communication systems has offered significant performance benefits, including being able to achieve spatial diversity through node cooperation [1], [2] and extending coverage without requiring large transmitter powers. Cooperative communication, therefore, has been an attractive option for use in cellular, ad-hoc networks and military communication systems [3]. The most common relaying protocols are Decode and Forward (DF) and Amplify and

Forward (AF). The AF scheme is a simple scheme, which amplifies the signal transmitted from the source and forwards it to the destination [4], [5], and unlike the DF scheme, no decoding at the relay is performed. AF techniques may use the knowledge of the statistics of the noise in addition to the knowledge of all channel state information to assist in the amplification of the signal.

The notion of information theoretic secrecy in communication systems was first introduced in [6]. The information theoretic secrecy requires that the received signal by an eavesdropper not provide any information about the transmitted messages. Following the pioneering works of [7] and [8] which have studied the wiretap channel, many extensions of the wiretap channel model have been considered from a perfect secrecy point of view (see e.g., [9], [10]).

Recently, AF MIMO relay systems have gained more attention from both academic and industrial communities, due to its simplicity and its benefits. The AF MIMO relay systems are, for example, adopted in future communication protocols such as LTE and IMT-advanced to enhance the coverage of base stations.

Most research works in MIMO cooperative communication systems have focused on the role of MIMO in enhancing the throughput and robustness. In this work, however, we focus on the role of such multiple antennas in enhancing wireless security. Particularly, in this paper, we consider a two-hop AF MIMO cooperative communication system in which there are no direct links between the source-destination and the source-eavesdropper nodes. Our goal is to maximize the physical layer security of the system with the constraint of limited available power at the source and the relay node. We formulate this problem as a non-convex constraint optimization problem. In the simplest scheme where all nodes have single antenna, we fully characterize the optimum relay strategy and show that when the available power is larger than a threshold, then the relay node does not need to consume all the available power. This is due to the fact that the secrecy capacity of the system will be saturated at high SNRs; therefore, using more power could not improve the secrecy capacity of the system. We then consider a scenario in which all the nodes except the intended receiver are equipped with multiple antennas. The significance of this model is when a base station wishes to broadcast secure information by the help of a relay node

Fig. 1. Secure Two-Hop Amplify & Forward (AF) Network System Model.

to small mobile units. In this scenario small mobile units have single antenna while the base station, the relay node, and the eavesdropper can afford multiple antennas. We characterize the optimum relay matrix and the transmitter covariance matrix by using the generalized eigenvectors of the channel state information matrices. Finally, we explicitly illustrate the optimum power allocation at the relay node.

II. PRELIMINARIES AND RELATED WORKS

A. Notation

In this paper, a vector will be written as a small bold letter (e.g. $\mathbf{x}$) and a matrix will be denoted by a capital bold letter (e.g. $\mathbf{A}$). The function $E[X]$ represents the statistical expectation of the random variable X and the function $\text{Tr}[\mathbf{A}]$ represents the trace value of the matrix $\mathbf{A}$. For a given matrix $\mathbf{A}$, its determinant is represented by $|\mathbf{A}|$.

B. System Model and Problem Statement

In this paper, we consider a secure wireless communication system where a source is communicating with the destination through a relay within the presence of an eavesdropper, as shown in Fig.1. In this model, we assume that all the nodes have N antennas and there are no direct links between the source-destination and the source-eavesdropper. Such a system may occur in many practical situations, as for example when two base stations equipped with multiple antennas communicate with each other via a relay node in the presence of an illegitimate eavesdropper.

The signal received by the destination and the eavesdropper are given as follows:

$$\mathbf{y} = \mathbf{H}_r \mathbf{G} (\mathbf{H}_1 \mathbf{x} + \mathbf{n}_1) + \mathbf{n}_r \quad (1)$$

$$\mathbf{z} = \mathbf{H}_e \mathbf{G} (\mathbf{H}_1 \mathbf{x} + \mathbf{n}_1) + \mathbf{n}_e$$

where $\mathbf{x}$ is the transmitted $n \times 1$ vector, and $\mathbf{H}_1$, $\mathbf{H}_r$, $\mathbf{H}_e$ are $n \times n$ channel gain matrixes from the source to the relay, and from the relay to the legitimate receiver and the eavesdropper, respectively. We assume that the relay node is in full duplex mode and amplifies the received signal by $\mathbf{G}$ and forwards it simultaneously (i.e. $\mathbf{v} = \mathbf{G}\mathbf{u}$). $\mathbf{n}_1$, $\mathbf{n}_r$, and $\mathbf{n}_e$ are the additive i.i.d Gaussian noise vectors with zero mean and covariance matrix $\mathbf{I}$ at the relay node, the intended receiver, and the eavesdropper, respectively. We assume that the transmitter is transmitting with power p and the relay node has access to maximum power of P , i.e.,

$$\begin{aligned} \text{Tr} [\mathbf{Q} \triangleq E [\mathbf{x}\mathbf{x}^\dagger]] &= P \\ \text{Tr} [\mathbf{G} (\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I}) \mathbf{G}^\dagger] &\leq P. \end{aligned} \quad (2)$$

In this paper we are interested in designing the optimum AF strategy for the relay node. We assume that the relay node has access to the all channel matrix gains. The secrecy Capacity of this system is given by the following optimization problem:

$$\begin{aligned} C_s = \max_{\mathbf{Q} \succeq 0, \mathbf{G}} \quad & \log \frac{|\mathbf{H}_r \mathbf{G} (\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I}) \mathbf{G}^\dagger \mathbf{H}_r^\dagger + \mathbf{I}|}{|\mathbf{H}_r \mathbf{G} \mathbf{G}^\dagger \mathbf{H}_r^\dagger + \mathbf{I}|} \\ & - \log \frac{|\mathbf{H}_e \mathbf{G} (\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I}) \mathbf{G}^\dagger \mathbf{H}_e^\dagger + \mathbf{I}|}{|\mathbf{H}_e \mathbf{G} \mathbf{G}^\dagger \mathbf{H}_e^\dagger + \mathbf{I}|} \end{aligned} \quad (3)$$

Such that:

$$\text{Tr} [\mathbf{Q}] \leq P, \text{Tr} [\mathbf{G} (\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I}) \mathbf{G}^\dagger] \leq P \quad (4)$$

The secrecy level of the confidential message W is measured at the eavesdropper in terms of

equivocation rate which is given by

$$R_e = H(W|\mathbf{Z}).$$

The perfect secrecy capacity C_s is the maximum amount of information that can be sent to the legitimate receiver in a reliable and confidential manner.

C. Related Works

For the Gaussian Multiple-Input Multiple-Output Multiple-Eavesdropper (MIMOME) channel (without relay node) and its extensions the works [9]–[11] have proved that the secrecy capacity of the channel is given by

$$C_s = \max_{\mathbf{Q} \succeq 0, \text{Tr}[\mathbf{Q}] \leq P} \frac{1}{2} \log \frac{|\mathbf{H}_r \mathbf{Q} \mathbf{H}_r^\dagger + \mathbf{I}|}{|\mathbf{H}_e \mathbf{Q} \mathbf{H}_e^\dagger + \mathbf{I}|}. \quad (5)$$

The above optimization problem involves solving a nonconvex problem. Usually nontrivial techniques and strong inequalities are used to solve the optimization problems of this type. In [11], the authors successfully characterized the capacity expression of the Gaussian Multiple-Input Single-Output Multiple-Eavesdropper (MISOME) channel in terms of generalized eigenvalues. We summarize the results of [11] here.

Definition 1 (Generalized eigenvalues): For a Hermitian matrix $\mathbf{A}$ and positive definite matrix $\mathbf{B}$, (λ, ψ) is referred to as a generalized eigenvalue-eigenvector pair of $(\mathbf{A}, \mathbf{B})$ if (λ, ψ) satisfy

$$\mathbf{A}\psi = \lambda\mathbf{B}\psi. \quad (6)$$

Generalized eigenvalues-eigenvectors have the following property:

Lemma 1 (Variational Characterization): The generalized eigenvectors of $(\mathbf{A}, \mathbf{B})$ are the stationary point solution to a particular Rayleigh quotient. Specifically, the largest generalized

eigenvalue is the maximum of the Rayleigh quotient

$$\lambda_{\max}(\mathbf{A}, \mathbf{B}) = \max_{\boldsymbol{\psi}} \frac{\boldsymbol{\psi}^\dagger \mathbf{A} \boldsymbol{\psi}}{\boldsymbol{\psi}^\dagger \mathbf{B} \boldsymbol{\psi}} \quad (7)$$

and the optimum is attained by the eigenvector corresponding to $\lambda_{\max}(\mathbf{A}, \mathbf{B})$.

For the MISOME channel of

$$\mathbf{y} = \mathbf{h}_r^\dagger \mathbf{x} + \mathbf{n}_r \quad (8)$$

$$\mathbf{z} = \mathbf{H}_e \mathbf{x} + \mathbf{n}_e,$$

[11] showed that the secrecy capacity is given by

$$\begin{aligned} C_s &= \max_{\mathbf{Q} \succeq 0} \frac{1}{2} \log \frac{|P \mathbf{h}_r^\dagger \mathbf{Q} \mathbf{h}_r + 1|}{|P \mathbf{H}_e \mathbf{Q} \mathbf{H}_e^\dagger + \mathbf{I}|} \\ &= \frac{1}{2} \log \lambda_{\max}(\mathbf{I} + P \mathbf{h}_r \mathbf{h}_r^\dagger, \mathbf{I} + P \mathbf{H}_e^\dagger \mathbf{H}_e). \end{aligned} \quad (9)$$

The optimum covariance matrix $\mathbf{Q}$ is given by

$$\mathbf{Q} = P \boldsymbol{\psi}_{\max} \boldsymbol{\psi}_{\max}^\dagger, \quad (10)$$

where $\boldsymbol{\psi}_{\max}$ is the normalized ¹ eigenvector corresponding to the pencil $(\mathbf{I} + P \mathbf{h}_r \mathbf{h}_r^\dagger, \mathbf{I} + P \mathbf{H}_e^\dagger \mathbf{H}_e)$

III. SINGLE ANTENNA SCHEME

In this section we consider the problem described in Fig.1, when all the nodes are equipped by only one antenna. By using the Lagrange Multiplier, the optimization problem of (3) and its constraints (4) can therefore be written as the following unconstrained problem:

$$\begin{aligned} C_s &= \max_g \log \frac{|g^2 h_r^2 (P h_1^2 + 1) + 1|}{|g^2 h_r^2 + 1|} \\ &\quad - \log \frac{|g^2 h_e^2 (P h_1^2 + 1) + 1|}{|g^2 h_e^2 + 1|} + \lambda (g^2 (P h_1^2 + 1) - P). \end{aligned} \quad (11)$$

¹In this paper we assume that the generalized eigenvectors are always normalized, i.e., $\boldsymbol{\psi}^\dagger \boldsymbol{\psi} = 1$.

The optimum value for g (which is denoted by g^*) is such that $\frac{\partial C_s}{\partial g} = 0$. Thus, after some mathematics we have

$$\frac{Ph_1^2(1 - g^{*4}h_r^2h_e^2(ph_1^2 + 1))}{M} + \lambda(Ph_1^2 + 1) = 0 \quad (12)$$

where,

$$M = (g^{*2}h_r^2(Ph_1^2 + 1) + 1)(g^{*2}h_e^2(Ph_1^2 + 1) + 1) \\ \times (g^{*2}h_r^2 + 1)(g^{*2}h_e^2 + 1). \quad (13)$$

Therefore, the optimum value for the relay gain is given as follows: When $\lambda \neq 0$, then the constraint must be satisfied; otherwise when $\lambda = 0$, g^* can be calculated from (12). Hence,

$$g^{*2} = \begin{cases} \frac{1}{h_r h_e \sqrt{Ph_1^2 + 1}}, & \lambda = 0; \\ \frac{P}{Ph_1^2 + 1}, & \lambda \neq 0. \end{cases} \quad (14)$$

As always, g^* must be such that $g^{*2} \leq \frac{P}{Ph_1^2 + 1}$, equivalently the above equation can be written as follows:

$$g^{*2} = \begin{cases} \frac{1}{h_r h_e \sqrt{Ph_1^2 + 1}}, & P \geq \frac{h_1^2 + \sqrt{h_1^4 + 4h_r^2h_e^2}}{2h_r^2h_e^2}; \\ \frac{P}{Ph_1^2 + 1}, & 0 \leq P \leq \frac{h_1^2 + \sqrt{h_1^4 + 4h_r^2h_e^2}}{2h_r^2h_e^2}. \end{cases} \quad (15)$$

As we can see from the above equation, when the power P is large enough, i.e., $P \geq \frac{h_1^2 + \sqrt{h_1^4 + 4h_r^2h_e^2}}{2h_r^2h_e^2}$, the relay node does not need to use all the power P . This is due to the fact that the secrecy capacity will saturate for high P s.

IV. MULTIPLE-INPUT MULTIPLE-RELAY SINGLE-OUTPUT MULTIPLE-EAVESDROPPER (MIMRSOME) SCHEME

In this section we consider the problem of Fig.1, when all the nodes except the intended receiver have access to multiple antenna. This model may occur in practice when the intended receiver is a mobile small unit that only can handle one antenna while the base station, the relay node, and the adversary eavesdropper are equipped by multiple antennas. The received signal by

the legitimate receiver and the eavesdropper is the same as (1) except that here, $\mathbf{H}_r$ is replaced by an $1 \times n$ vector of $\mathbf{h}_r^\dagger$ and the $n \times 1$ noise vector $\mathbf{n}_r$ is replaced by a scalar noise n_r .

The optimization problem of (3) and its constraints (4) can therefore be written as follows:

$$C_s = \max_{\mathbf{Q} \succeq 0, \mathbf{G}} \log \frac{\left| \mathbf{h}_r^\dagger \mathbf{G} \left(\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I} \right) \mathbf{G}^\dagger \mathbf{h}_r + \mathbf{I} \right|}{\left| \mathbf{H}_e \mathbf{G} (\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I}) \mathbf{G}^\dagger \mathbf{H}_e^\dagger + \mathbf{I} \right|} \quad (16)$$

$$+ \log \frac{\left| \mathbf{H}_e \mathbf{G} \mathbf{G}^\dagger \mathbf{H}_e^\dagger + \mathbf{I} \right|}{\left| \mathbf{h}_r^\dagger \mathbf{G} \mathbf{G}^\dagger \mathbf{h}_r + \mathbf{I} \right|}$$

Such that:

$$\text{Tr}[\mathbf{Q}] \leq P, \text{Tr} \left[\mathbf{G} \left(\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I} \right) \mathbf{G}^\dagger \right] \leq P. \quad (17)$$

Let us define $\mathbf{Q}_1$ and $\mathbf{Q}_2$ as follows:

$$\mathbf{Q}_1 \triangleq \mathbf{G} \left(\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I} \right) \mathbf{G}^\dagger \quad (18)$$

$$\mathbf{Q}_2 \triangleq \mathbf{G} \mathbf{G}^\dagger.$$

According to (17), $\mathbf{Q}_1$ and $\mathbf{Q}_2$ must be such that

$$\text{Tr}[\mathbf{Q}_1] \leq P, \quad (19)$$

$$\text{Tr} \left[\mathbf{G} \mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger \mathbf{G}^\dagger \right] + \text{Tr}[\mathbf{Q}_2] \leq P. \quad (20)$$

Let us define x as,

$$x \triangleq \text{Tr} \left[\mathbf{G} \mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger \mathbf{G}^\dagger \right]. \quad (21)$$

The optimization problem is therefore as follows:

$$C_s = \max_{\mathbf{Q}_1 \succeq 0, \mathbf{Q}_2 \succeq 0} \log \frac{|\mathbf{h}_r^\dagger \mathbf{Q}_1 \mathbf{h}_r + \mathbf{I}|}{|\mathbf{H}_e \mathbf{Q}_1 \mathbf{H}_e^\dagger + \mathbf{I}|} + \log \frac{|\mathbf{H}_e \mathbf{Q}_2 \mathbf{H}_e^\dagger + \mathbf{I}|}{|\mathbf{h}_r^\dagger \mathbf{Q}_2 \mathbf{h}_r + \mathbf{I}|} \quad (22)$$

such that:

$$\text{Tr}[\mathbf{Q}_1] \leq P, \text{Tr}[\mathbf{Q}_2] \leq P - x. \quad (23)$$

This problem can be viewed as two independent optimization problems of type problem (9). Let $(\lambda_{\max}, \boldsymbol{\psi}_{\max})$ be the maximum generalized eigenvalue and its corresponding eigenvector of the following pencil:

$$(\mathbf{I} + P\mathbf{h}_r\mathbf{h}_r^\dagger, \mathbf{I} + P\mathbf{H}_e^\dagger\mathbf{H}_e). \quad (24)$$

Similarly, let $(\gamma_{\max}, \boldsymbol{\varphi}_{\max})$ be the maximum generalized eigenvalue and its corresponding eigenvector of the following pencil:

$$(\mathbf{I} + (P - x)\mathbf{H}_e^\dagger\mathbf{H}_e, \mathbf{I} + (P - x)\mathbf{h}_r\mathbf{h}_r^\dagger). \quad (25)$$

Therefore, according to (10) the optimum values for $\mathbf{Q}_1$ and $\mathbf{Q}_2$ are given by

$$\mathbf{Q}_1 = \mathbf{G} \left(\mathbf{H}_1 \mathbf{Q} \mathbf{H}_1^\dagger + \mathbf{I} \right) \mathbf{G}^\dagger = P \boldsymbol{\psi}_{\max} \boldsymbol{\psi}_{\max}^\dagger \quad (26)$$

$$\mathbf{Q}_2 = \mathbf{G} \mathbf{G}^\dagger = (P - x) \boldsymbol{\varphi}_{\max} \boldsymbol{\varphi}_{\max}^\dagger, \quad (27)$$

and the secrecy capacity is as follows:

$$C_s = \frac{1}{2} \log \lambda_{\max} \gamma_{\max}. \quad (28)$$

A straightforward solution for the equation of (27) is as follows:

$$\mathbf{G} = \sqrt{P - x} \left[\boldsymbol{\varphi}_{\max} \mid \mathbf{0}_{n \times (n-1)} \right], \quad (29)$$

where $\mathbf{0}_{n \times (n-1)}$ is an $n \times (n-1)$ all zero matrix. By substituting (29) into (26), the covariance matrix of $\mathbf{Q}$ is given by

$$\mathbf{Q} = (\mathbf{G}\mathbf{H}_1)^{-1} [P\boldsymbol{\psi}_{\max}\boldsymbol{\psi}_{\max}^\dagger - (P-x)\boldsymbol{\varphi}_{\max}\boldsymbol{\varphi}_{\max}^\dagger] \times (\mathbf{H}_1^\dagger\mathbf{G}^\dagger)^{-1}, \quad (30)$$

where $\mathbf{G}$ is as (29).

To calculate the optimum value of x , note that

$$\begin{aligned} x &= \text{Tr} [\mathbf{G}\mathbf{H}_1\mathbf{Q}\mathbf{H}_1^\dagger\mathbf{G}^\dagger] \\ &\stackrel{(a)}{=} \text{Tr} [\mathbf{H}_1^\dagger\mathbf{G}^\dagger\mathbf{G}\mathbf{H}_1\mathbf{Q}] \\ &\stackrel{(b)}{=} \text{Tr} [(P-x)\mathbf{H}_1^\dagger\boldsymbol{\psi}_{\max}\boldsymbol{\psi}_{\max}^\dagger\mathbf{H}_1\mathbf{Q}] \\ &\stackrel{(c)}{\leq} (P-x) \left[\text{Tr} [\mathbf{H}_1^\dagger\boldsymbol{\psi}_{\max}\boldsymbol{\psi}_{\max}^\dagger\mathbf{H}_1] \text{Tr} [\mathbf{Q}] \right] \\ &\stackrel{(d)}{=} (P-x) P \|\mathbf{H}_1^\dagger\boldsymbol{\psi}_{\max}\|^2, \end{aligned} \quad (31)$$

where (a) follows from the fact that $\text{Tr}[\mathbf{AB}] = \text{Tr}[\mathbf{BA}]$, (b) follows from (27), (c) follows from the fact that for any $\mathbf{A} \succ \mathbf{0}$ and $\mathbf{B} \succ \mathbf{0}$, $\text{Tr}[\mathbf{AB}] \leq \text{Tr}[\mathbf{A}] \text{Tr}[\mathbf{B}]$, and (d) follows from the fact that $\text{Tr}[\mathbf{AA}^\dagger] = \|\mathbf{A}\|^2$, where $\|\cdot\|$ represents the Frobenius norm of a matrix.

From the inequality of (31), x is bounded as follows:

$$x \leq \frac{P^2}{1 + P \|\mathbf{H}_1^\dagger\boldsymbol{\psi}_{\max}\|^2}. \quad (32)$$

Now, we must choose the parameter x such that maximizes C_s which is given by

$$\begin{aligned} C_s &= \frac{1}{2} \log \lambda_{\max} \gamma_{\max} \\ &= \frac{1}{2} \log \lambda_{\max} \frac{1 + (P-x) \|\mathbf{H}_e \boldsymbol{\varphi}_{\max}(x)\|^2}{1 + (P-x) |\mathbf{h}_r^\dagger \boldsymbol{\varphi}_{\max}(x)|^2} \end{aligned} \quad (33)$$

with the constraint of (32). Note that in the above optimization problem $\lambda_{\max}$ is independent of

x , however, $\varphi_{\max}$ is a function of x , i.e.,

$$\varphi_{\max}(x) = \arg \max_{\varphi} \frac{1 + (P - x) \|\mathbf{H}_e \varphi\|^2}{1 + (P - x) |\mathbf{h}_r^\dagger \varphi|^2}. \quad (34)$$

Thus, to obtain the optimum value of x we need a more explicit relationship between x and $\gamma_{\max}$. For this purpose, note that $(\gamma_{\max}, \varphi_{\max})$ are the maximum generalized eigenvalue- eigenvector pair of pencil (25). Hence,

$$\begin{aligned} & |(1 - \gamma_{\max}) \mathbf{I} + (P - x) [\mathbf{H}_e^\dagger \mathbf{H}_e - \gamma_{\max} \mathbf{h}_r \mathbf{h}_r^\dagger]| \\ &= 0. \end{aligned} \quad (35)$$

In general we have,

$$|\mathbf{I} + \mathbf{A}| = \sum_{k=0}^{\infty} \left(- \sum_{j=1}^{\infty} \frac{(-1)^j}{j!} \text{Tr} [\mathbf{A}^j] \right)^k, \quad (36)$$

therefore equation (35) is equivalent to the following equation:

$$\begin{aligned} & \sum_{k=0}^{\infty} \frac{1}{k!} \left(- \sum_{j=1}^{\infty} \frac{(-1)^j}{j!} \frac{P - x}{1 - \gamma_{\max}} \text{Tr} [(\mathbf{H}_e^\dagger \mathbf{H}_e - \gamma_{\max} \mathbf{h}_r \mathbf{h}_r^\dagger)^j] \right)^k \\ &= 0. \end{aligned}$$

The above equation, explicitly, characterizes $\gamma_{\max}$ as a function of x (or $P - x$). By solving this problem and setting $\frac{\partial \gamma_{\max}}{\partial x} = 0$, we can determine the optimum power allocation of the relay node (which is $P - x$). Note that the optimum power allocation must always satisfy the constraint of (32).

V. CONCLUSIONS

We considered a two-hop AF MIMO cooperative communication system in which there are no direct links between the source-destination and the source-eavesdropper nodes. We maximized the physical layer security of the system with the constraint of limited available power at the source and the relay node. When all the nodes have single antenna, we fully characterized the optimum relay strategy and showed that when the available power is larger than a threshold,

then the relay node need not consume all the available power. Motivated by the fact that mobile units usually can afford only a single antenna, we then considered a scenario in which all the nodes (except the intended receiver) are equipped with multiple antennas. We characterized the optimum relay matrix and the transmitter covariance matrix by using the generalized eigenvectors of the channel state information matrices. Finally, we explicitly illustrated the optimum power allocation at the relay node.
